Fairbanks, Alaska 99709-3645

INTRODUCTION

Monitoring of Interior Alaska streams in placer mined areas continued during the 1998 field season by Alaska Hydrologic Survey investigators. This study is a combined effort of the Alaska Department of Natural Resources Division of Mining and Water Management (ADNIUDMWM), and the Alaska Department of Environmental Conservation (ADEC). Results from similar studies carried out in previous field seasons can be found in Ray (1992), Ray (1991), Ray (1990), Ray (1989), Mack et al. (1988), Mack et al. (1987), Mack and Moorman (1987), and Mack and Moor-man (1986).

Sampling sites were selected based on location, proximity to current mining activities, and past history of sampling. Automated water samplers were used to collect samples from each site on a daily basis, which were then analyzed for turbidity and total suspended solids. Though not a conclusive measure of overall water quality, turbidity and total suspended solids are a good measure for quantifying the visual clarity of water. During 1998 four waterbodies were monitored, the results of which are contained in this report.

METHODS

Field

As shown in Figure 1, four locations were selected for monitoring in 1998:

- Birch Creek at Mile 147 Steese Highway Bridge
- Crooked Creek in Central
- Birch Creek at 98 Mile Steese Highway
- Little Chena River at Mile 12 Chena Hot Springs Road

Birch Creek at Mile 147 Bridge is located approximately 25 road miles east of Central, and has been a long term monitoring station throughout these continuing studies. The basin area is approximately 2,150 square miles, and includes flows from the north and south sides of Eagle Summit, including the Crooked Creek basin. Crooked Creek in Central is monitored from a location upstream of the Steese Highway Bridge, and has a basin area of 167 square miles. The Crooked Creek drainage includes Porcupine, Bonanza, Boulder, Bedrock as well as numerous other creeks. Birch Creek at 98 Mile Steese is located at the downstream end of what is commonly referred to as the "98 Mile reclamation site". This site was reclaimed in 1995 in conjunction with the resurfacing of the Steese Highway, as gravel was authorized for use by the contractor from this location. The site is just upstream of the previous "Birch Creek above Twelve Mile Creek" location, and has a combined basin area of 67 square miles, combining Eagle, Ptarmigan, Gold Dust, Butte Creeks, as well as others. The traditional "Birch Creek above Twelve Mile Creek" monitoring site would have been used, but a new parking/canoe launch area was constructed and provides good access to the creek. While that has advantages from a

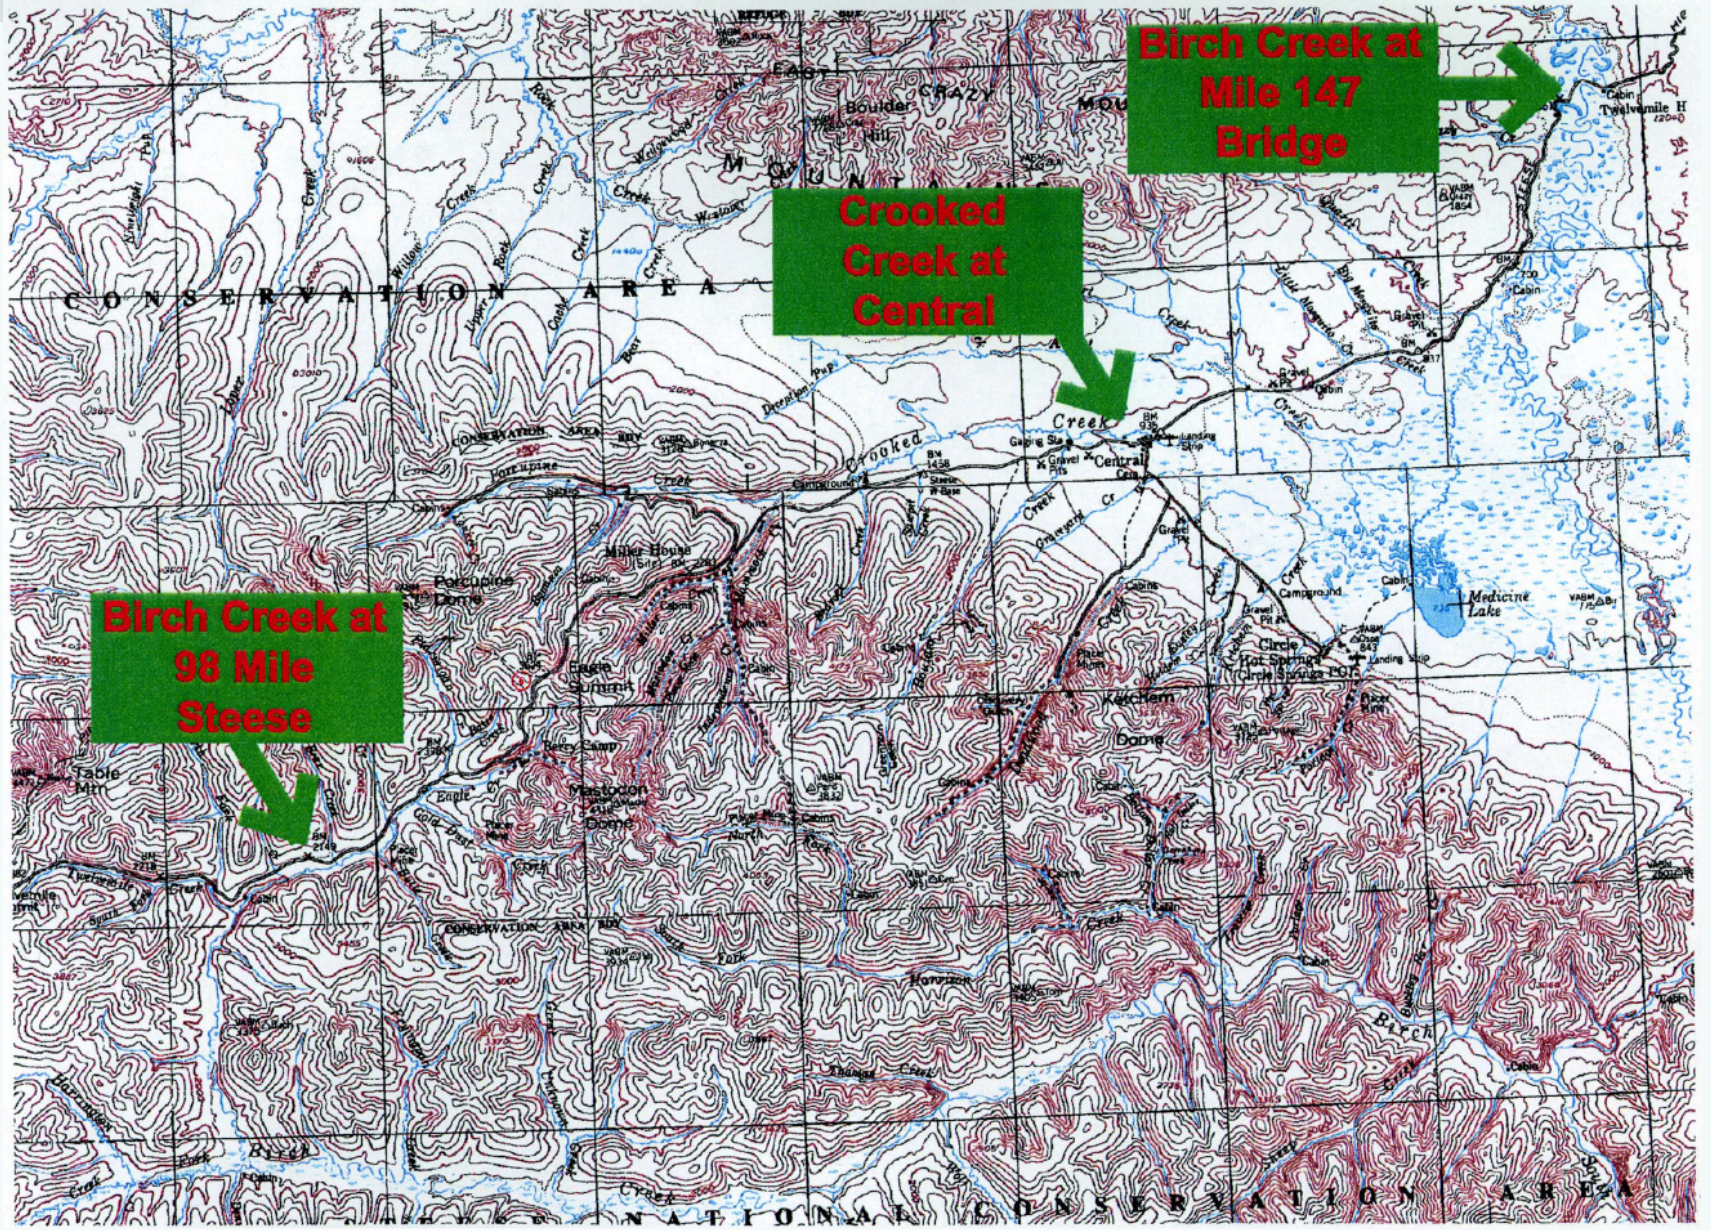

Figure 1 a. Map of monitoring sites, located approximately 100 miles northeast of Fairbanks, Alaska.

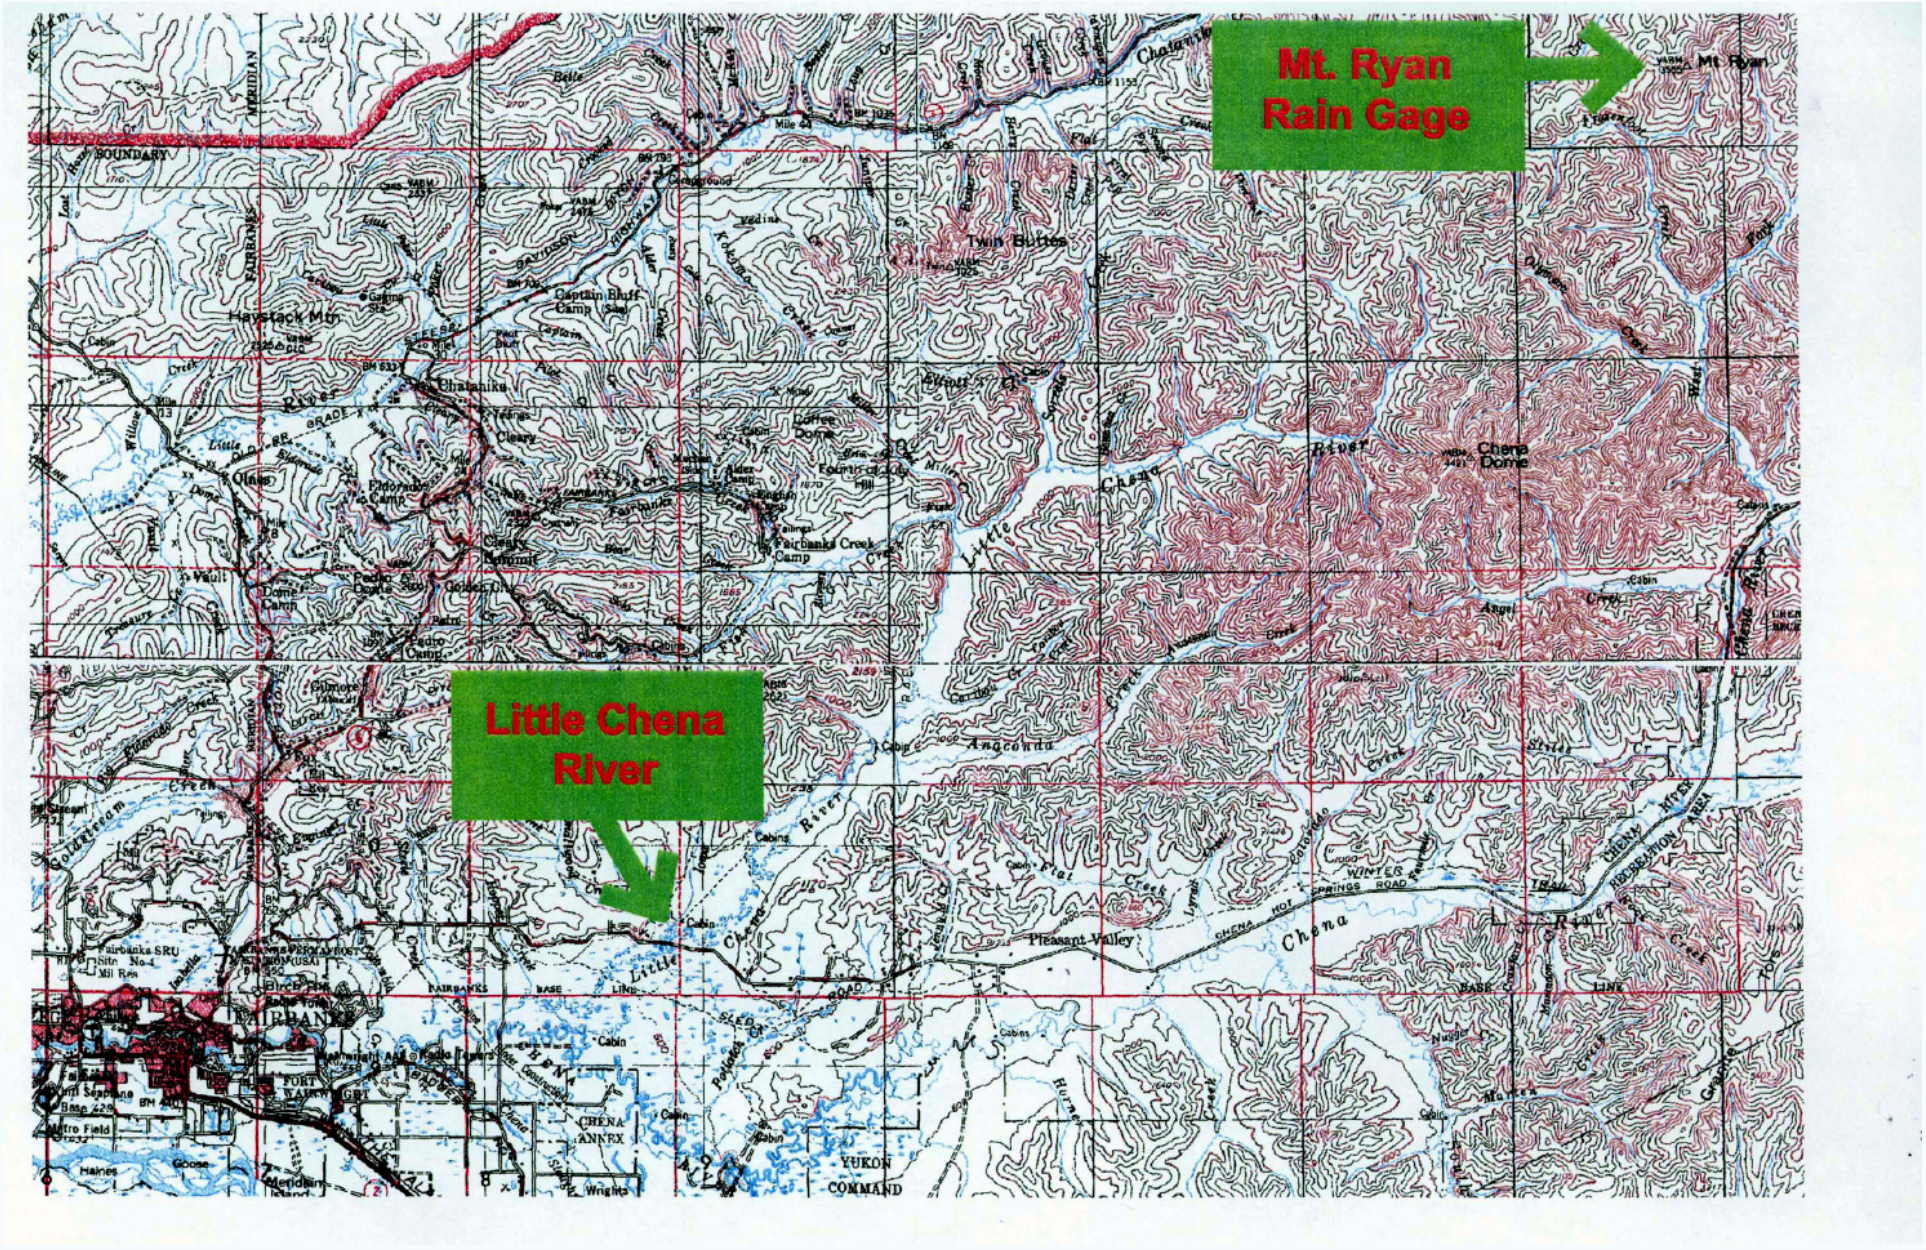

Figure lb. Map of monitoring sites, located approximately 15 miles east of Fairbanks, Alaska.

site servicing point of view, it also makes it easier for the general public to access the sampling location and would increase the probability of vandalism. The more remote site at 98 Mile Steese Highway was chosen. The Little Chena River site is located at Mile 12 on Chena Hot Springs Road, east of Fairbanks. The basin area is 372 square miles.

Equipment for this project includes an automated water sampler commonly referred to as an "ISCO", which derives its name from ISCO, Inc. (Lincoln, Nebraska), the manufacturer of these particular samplers (the use of brand or trade names in this report is for descriptive purposes only and does not constitute endorsement). The samplers are programmed to collect a sample of water four times a day, at six hour intervals, into one bottle. Each day, a new sample bottle is filled with four aliquots of stream water. This one sample bottle from each day represents a "daily average" sample to be analyzed for selected parameters. Unless the sampling location is on the power grid, as is the case. at the Little Chena River station, the samplers are powered by common 12 volt lead-acid batteries. The sampling pump is a simple peristaltic pump using a length of silicon tubing, connected to a longer length of vinyl tubing which is secured in the creek. At a pre-determined time, the pump turns on in reverse to purge the sample line, then pumps forward to collect a sample into the appropriate bottle. Depending on the model , sample bottles hold either 500 mL or 1000 mL, and each sampler holds either 24 or 28 bottles. The sites are serviced regularly to collect the samples for lab analysis.

The field installation is designed on a site-by-site basis, depending on the stream morphology and the particular situation. For the extent of this project, a typical installation is shown in Figure 2. The ideal location for the sampling site is a relatively

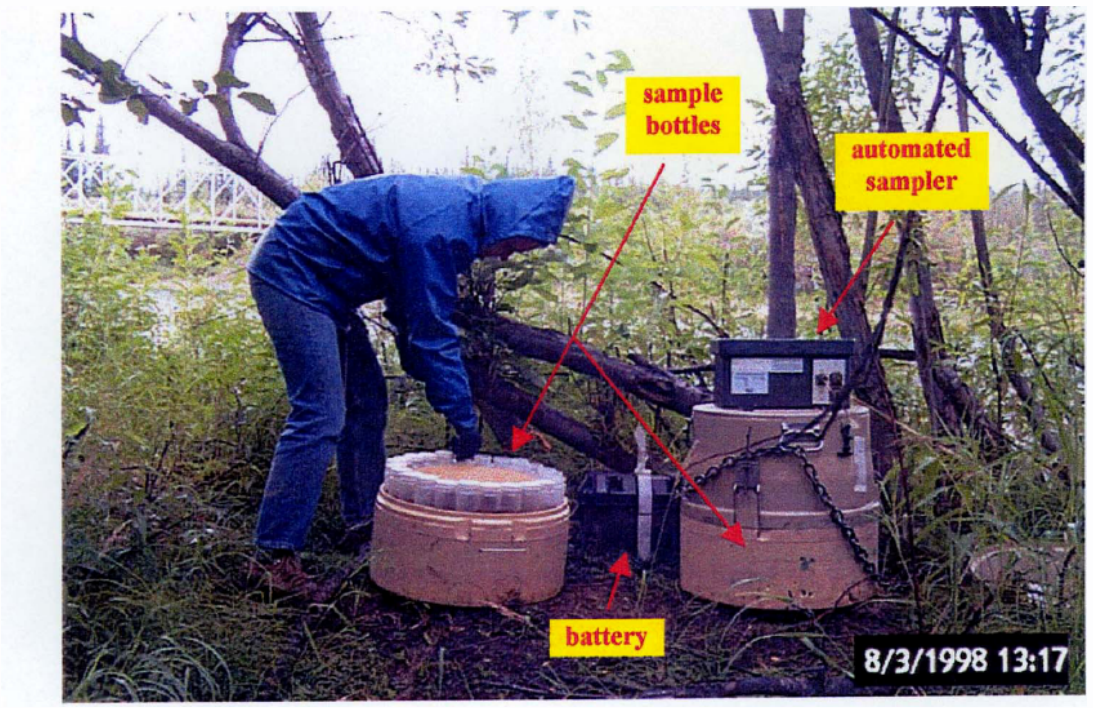

Figure 2. Monitoring equipment at Birch Creek at Mile 147 Bridge.

straight reach of the creek in which the thalweg is located near the bank selected to put the equipment on. An alternative is to place the equipment in a flood protected backwater. If such a location is utilized, care must be taken to ensure that the sample is not taken in stagnant water. In either case, it is desirable that the equipment be chained in place to deter theft and protect against equipment loss in case of an extreme flood event.

For stabilization purposes, a 7-foot steel fence post is driven into the stream bed at the desired location. A 3-foot steel staff gage is wired to a length of ¾-inch pvc pipe. The end of the vinyl suction tube is also wired to the pvc pipe such that the end of the hose is approximately six inches above the stream bed. Finally, the pvc pipe is connected to the fence post with hose clamps. This method provides a functional location from which to collect data, which is easily serviced when necessary.

A volunteer weather observer from the National Weather Service measured precipitation at Crooked Creek in Central during the summer of 1998. The observer recorded daily readings and reported them to the National Weather Service in Fairbanks on a monthly basis. Data was also utilized from a gage operated by the National Weather Service atop Mt. Ryan, located near the headwaters of the Little Chena River. These data were gathered by a remotely operated tipping bucket and relayed by way of satellite communications.

Laboratory

Laboratory analysis of the water samples was contracted to Boreochem Mobile Lab & Consulting, of Fairbanks, Alaska. Analytical methods followed those developed by the U.S. Environmental Protection Agency (EPA). Specifically, turbidity was analyzed using EPA method 180.1, which specifies use of a nephelometer calibrated against standard solutions. Analyses are reported in nephelometric turbidity units (NTU). Total suspended solids were analyzed using the gravimetric procedure outlined in EPA method 160.2 whereby a known volume of the sample is filtered through a tared glass fiber filter. The filter is dried in an oven at $105^{o}C$ until a constant weight is obtained, usually overnight. The filter is then weighed and the mass of the remaining residue is reported with respect to the initial volume sampled for analysis, in milligrams per liter (mg/L).

RESULTS

Each sampling location has its own characteristics which can govern the quantity and quality of data that can be reasonably collected. Summary statistics for turbidity and total suspended solids analyses are found in Tables 1 and 2. Complete results are found in Appendix A for each site monitored. Precipitation data are shown in Figure 3 for the Crooked Creek at Central site and in Figure 4 for the Mt. Ryan site; the numerical values are found in Appendix B.

DISCUSSION

As would be expected in an area of regional non-point sediment inputs, rainfall plays a major role in the explanation of stream sediment values at our monitoring locations, In the area covered by the four gage sites, orographic conditions, basin aspect, storm track direction, atmospheric conditions and basin effects maximize the variability of location and intensity of any given rain event. As seen in Figure 3, a fairly large storm event occurred in the Central area between 7 July and 13 July; 2.97 inches of rain fell over the seven days. This storm approximates the five year-7 day precipitation event (Miller, 1965). This rainfall was mirrored in the sediment graphs of Birch Creek at Mile 147 Bridge, Crooked Creek and Birch Creek at 98 Mile Steese as shown in Figures 6, 7, and 8. The storm event did not involve the Little Chena basin and there is no sign of sediment increase over that period of time in Figure 5.

Increased flow resulted from the intense rainstorm in the Crooked Creek basin, causing a failure of the stream bank where the sampling equipment was located . The ISCO sampler was chained to a large tree, and was not swept away. However, the fence post, staff gage, sample tubing and other monitoring devices were washed away and not recovered. Overall, 23 sampling days were lost due to this event. Because of this stream modification, the gage site was relocated approximately 150 feet upstream. As seen in Figures 5 through 8, there are some short term data gaps. These are primarily the result of operator or equipment malfunction, and are on the order of one to three days lapsed sampling time.

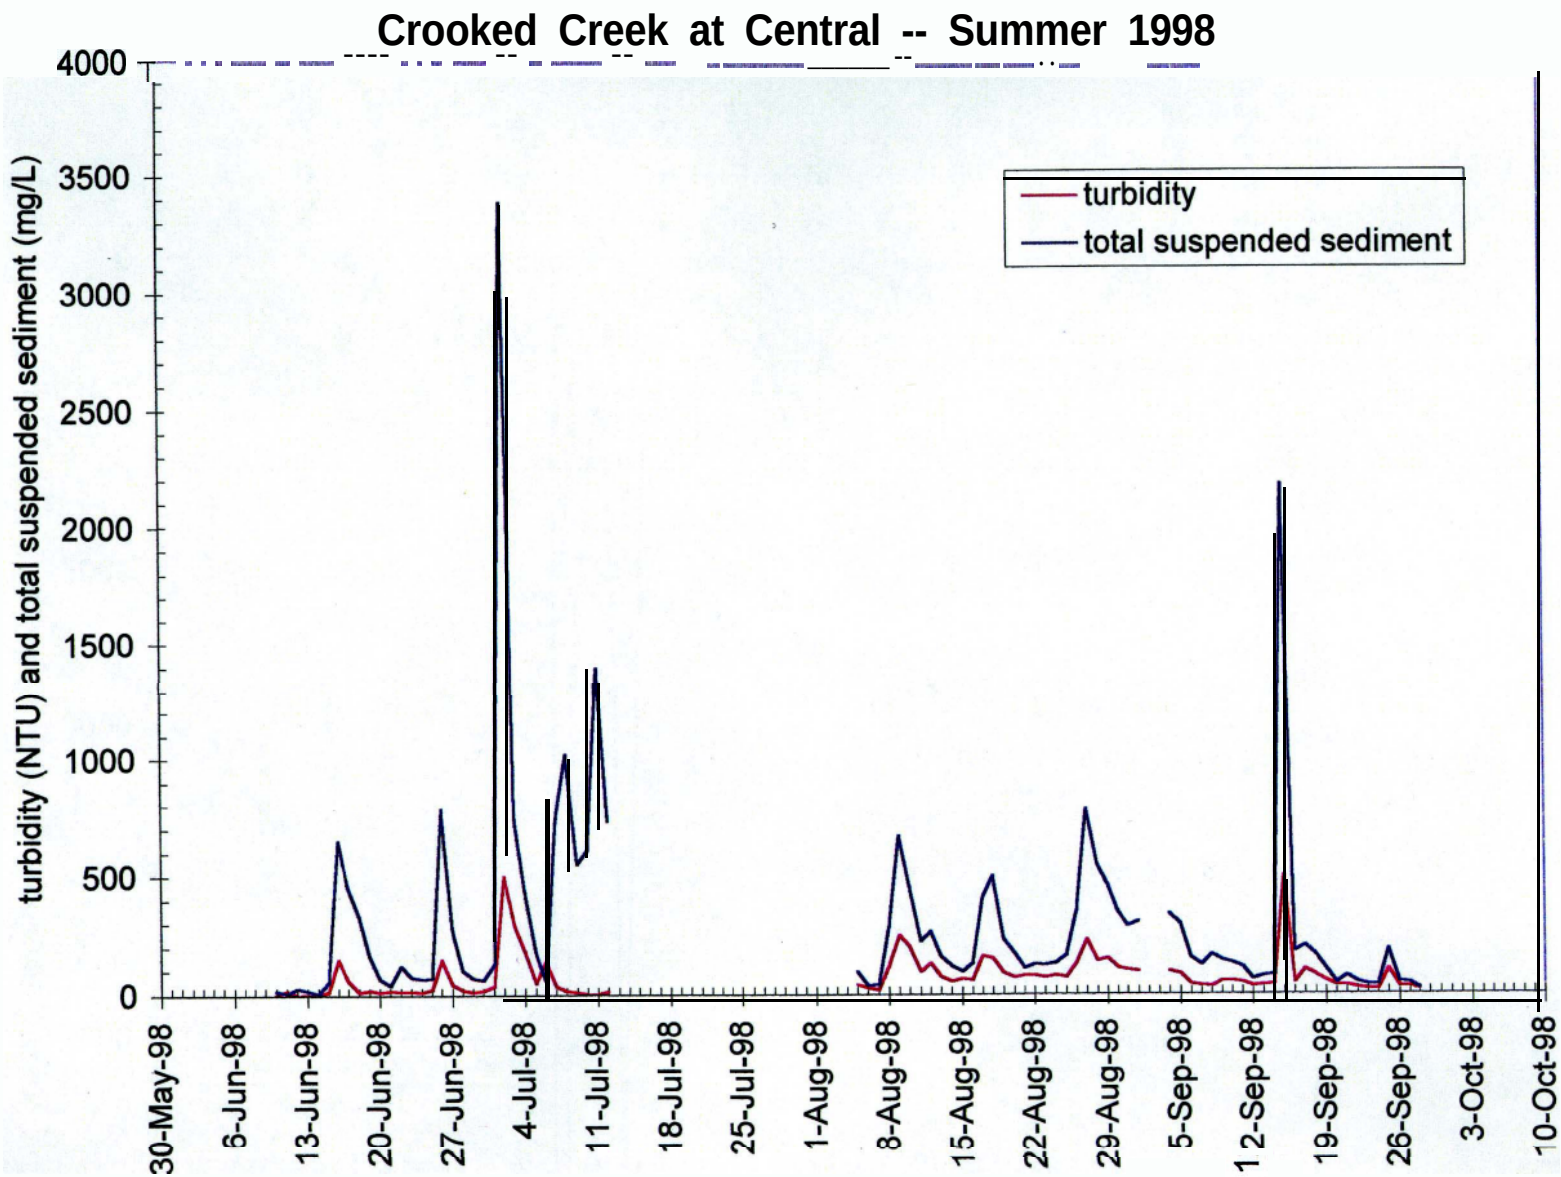

Figure 8. Turbidity and total suspended solids, Crooked Creek at Central, Summer 1998.

There is a record of historical monitoring at three of the four sites monitored in 1998. The trends of the median turbidity for each year monitored are shown in Figure 9, and are found in tabulated form in Appendix C. Birch Creek at Mile 147 Bridge has the longest period of record and it appears that while great progress has been made in minimizing the turbidity in the past few years, the trend was not sustained in 1998. Crooked Creek appears to be following a similar trend of lower turbidity until 1998, where a very dramatic increase in median turbidity is seen. The initial thought is that this could be attributed in part to the bank collapse at the gage site. But in reality, that served to minimize the turbidity values represented in Figure 9 because the sampler was not operational for the period of time when sediment input was the greatest. It should be

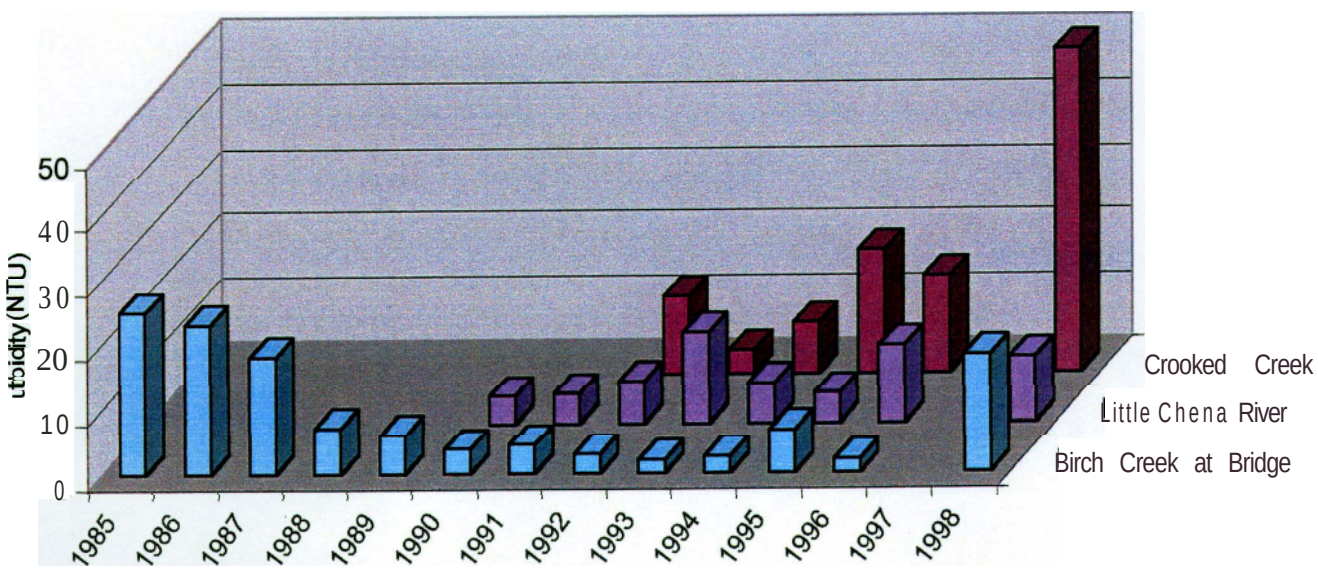

Figure 9. Historical record at three long-term gage sites, showing annual median turbidity values over time (no samples collected in 1997).

realized that bank failures such as that which occurred at the gage site on Crooked Creek are a normal part of stream dynamics. There will always be a storm event of a magnitude great enough to adjust the morphology of any stream. Sediment analyses in the Little Chena River appear to be somewhat consistent since monitoring began in 1990.

As shown in Figure 10, each of the four locations exhibits a characteristic pattern of turbidity values. Analysis of the Little Chena River samples indicates that more than 80% of the data are less than 20 NTU. This implies generally good water quality, with some outliers that are most likely the result of storm events. At Birch Creek at 98 Mile Steese however, only slightly more than 30% of the data are less than 20 NTU, indicating that more of a chronic elevation of turbidity exists in the samples from this season at this location.

It should be noted that site-specific conditions can serve to increase the variables that might alter these frequencies from season to season. These can include monitoring locations, monitoring frequency, surface activities, and rainfall regime. Although the best effort is made to collect as many samples as possible at a given site, there are some gaps in the data which would tend to add variability when comparing data over the course of several seasons. The gap in data from the Birch Creek at Mile 147 Bridge between 19 June and 6 July was the result of vandalism. At this location, the cable connecting the battery to the sampler was disconnected, interrupting the sampling routine until the site was serviced and the damage repaired.

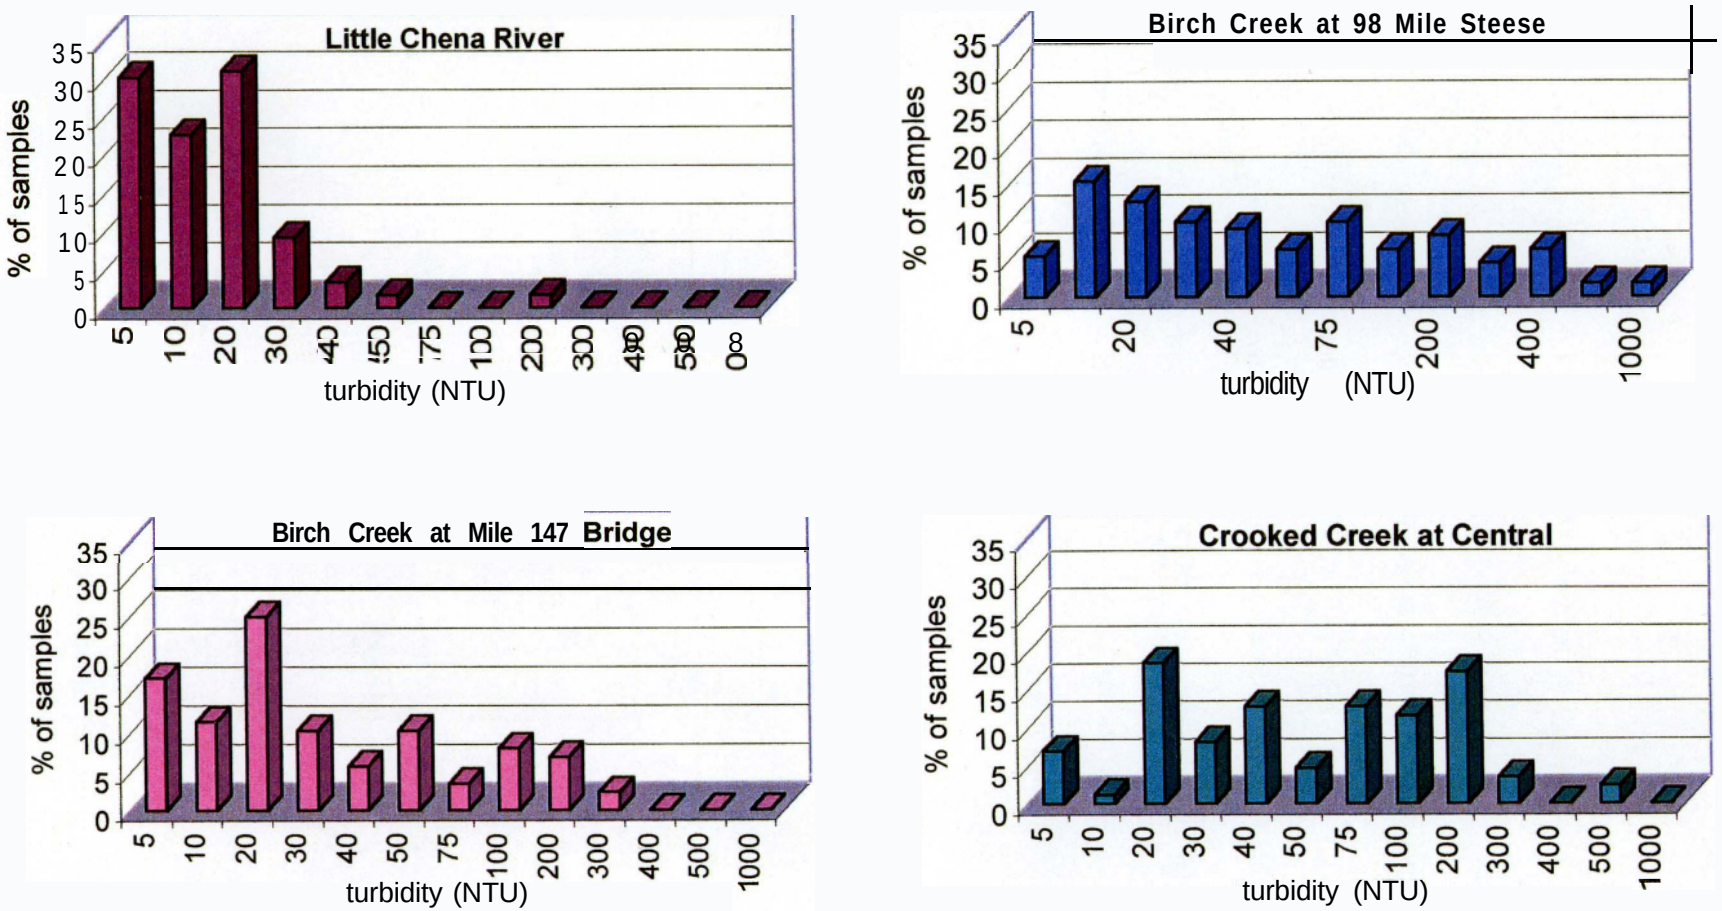

Figure 10. Frequency of occurrence of various levels of turbidity.

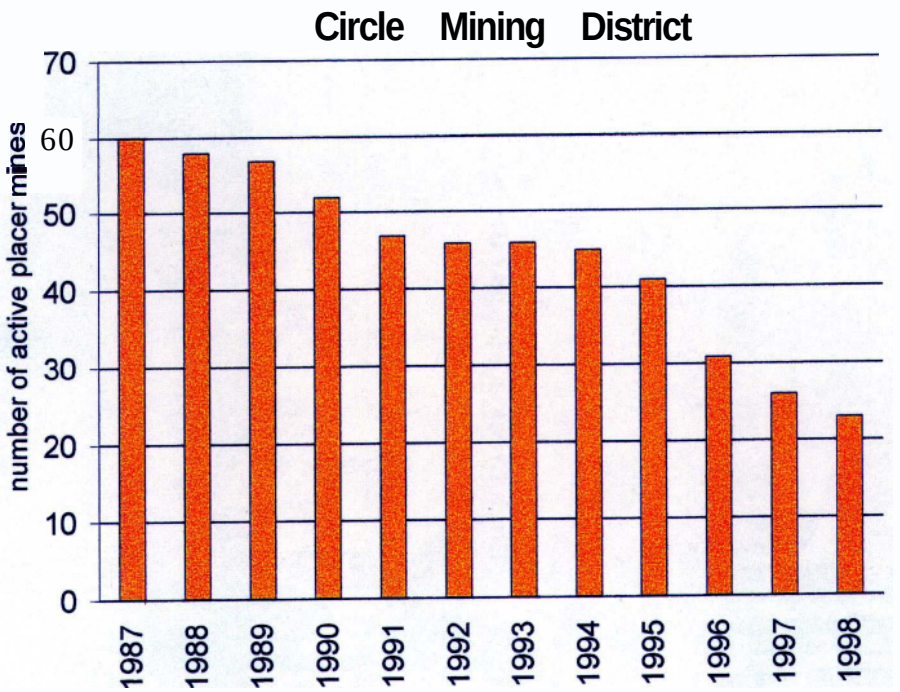
As shown in Figure 11, surface activity has changed over the years in the Circle Mining District. Due to gradual depletion of ore reserves and a decrease in the price of gold, the number of active placer mines in the district has continued to fall. Despite this decreasing trend in surface activity, the water quality appeared to decrease in 1998. Although this study cannot conclusively identify whether the main source of this degradation is from point or non-point pollution, historic or active placer mining, natural conditions, or a combination of these, it is a common perception that enforcement of water quality standards and best management practices by the appropriate agencies (i.e. Department of Natural Resources, Department of Environmental Conservation, Bureau of Land Management, among others) is a critical requisite for the water quality to improve at these monitoring sites.



F'igure 11. Number of active placer mines, Circle District, 1987- 1998.

CONCLUSIONS and RECOMMENDATIONS

- Although a storm-induced bank collapse temporarily interrupted the monitoring at the Crooked Creek at Central location, the large rise in median turbidity at this site as compared to previous years is not attributed to the bank failure.

- Data collected may not show a change in historic trends, but rather an anomalous year. Changes in long term trends should be documented over the "long term". This may be an indicator of such a change, and suggests that further monitoring is warranted.

- The frequency of various levels of turbidity reflect more of a persistent water quality issue than would be expected at three of the locations where monitoring took place in 1998.

- Although the number of active placer mines continues to decrease in the Circle Mining District, it is recommended that water quality standards be actively enforced to assure consistency with the State's water quality standards.

Acknowledgments

Field assistance was provided by Amy Ash of the Alaska Department of Environmental Conservation.

Mr. Jim Vohden:

RE: Report # 1738: results of Total Suspended Solids and Turbidity analysis of aqueous samples.

Following are results of the Total Suspended Solids,(TSS), and Turbidity analysis of aqueous samples delivered to Boreochem on July 9, 1998 , tested by SM 2540D and SM 2130B, respectively. Total Suspended Solids results are reported in mg/L; turbidity results are reported in nephelometric turbidity units. (NTU)

Turbidity tests were conducted on July 14. 1998; TSS analyses were conducted on July 16, 1998.

Results presented here are identical to those transmitted to you electronically at an earlier date.

Please Note:

LCR = Lower Chena River.
CCR= Crooked Creek.
BCAB= Birch Creek At Bridge.
BCB98= Birch Creek Below 98 Mile.

If you have any questions or comments about these results. please do not hesitate to give me a call.

Sincerely.

Boreochem Laboratories, Inc.

Mr. Jim Vohden:

RE: Report # 1758: Results of Total Suspended Solids and Turbidity analysis of aqueous samples.

Following are results of the Total Suspended Solids,(TSS), and Turbidity analysis of aqueous samples delivered to Boreochem on August 4, 1998 , tested by SM 2540D and SM 2130B, respectively . Total Suspended Solids results are reported in mg/L; turbidity results are reported in nephelometric turbidity units, (NTU)

Turbidity tests were conducted on August 13, 1998; TSS analyses were conducted on August 17, 1998.

Results presented here are identical to those transmitted to you electronically at an earlier date.

Please Note:

LCR = Little Chena River.
CCR= Crooked Creek.
BCAB= Birch Creek At Bridge.
BCB98= Birch Creek Below 98 Mile.

If you have any questions or comments about these results, please do not hesitate to give me a call.

Sincerely,

Boreochem Laboratories, Inc.

Tim Thomas
Laboratory Director

Mr. Jim Vohden:

RE: Report # 1825: Results of Total Suspended Solids and Turbidity analysis of aqueous samples.

Following are results of the Total Suspended Solids,(TSS), and Turbidity analysis of aqueous samples delivered to Boreochem on November 19, 1998, tested by SM 2540D and SM 2 1305, respectively Total Suspended Solids results are reported in mg/L; turbidity results are reported in nephelometric turbidity units, (NTU) .

Turbidity tests were conducted on November 20, 1998; TSS analyses were conducted on November 21, 1998

Results presented here are identical to those transmitted to you electronically at an earlier date.

Please Note:

LCR = Little Chena River.
CC= Crooked Creek.
B@BR= Birch Creek At Bridge.
BC@98= Birch Creek Below 98 Mile.

The following sample bottles did not contain aqueous sample for testing :

BC@98 9/28/98	BC@98 9/29/98	BC@98 10/1/98
BC@98 10/2/98	BC@98 10/3/98	BC@98 10/4/98
BC@98 10/5/98	BC@98 10/6/98	BC@98 10/7/98
CC 9/29/98	CC 9/30/98	

If you have any questions or comments about these results, please do not hesitate to give me a call.

Sincerely,

Boreochem Laboratories, Inc.

Tim Thomas
Laboratory Director
